- “Policyholder” i is followed over time $t = 1, \dots, 9$ years
- Unit of analysis “ it ”
- Have available: exposure e_{it} and covariates (explanatory variables) \mathbf{x}_{it}
 - Covariates often include age, gender, vehicle type, driving history and so forth
- Goal: Understand how time t and covariates impact claims y_{it} .
- Statistical Methods Viewpoint
 - Basic regression set-up - almost every analyst is familiar with.
 - It is part of the basic actuarial education curriculum
 - Incorporating cross-sectional and time patterns is the subject of longitudinal data analysis - a widely available statistical methodology

- Variations - motivated by insurance company records
- For each it , could have multiple claims, $j = 0, 1, \dots, 5$
- For each claim (y_{itj}) , consider different types the financial impact.
 - $y_{itj,1}$ - claim for injury to a party other than the insured - “injury”;
 - $y_{itj,2}$ - claim for damages to the insured, including injury, property damage, fire and theft - “own damage”; and
 - $y_{itj,3}$ - claim for property damage to a party other than the insured - “third party property”.
- Distribution for each claim is typically medium to long-tail
- The full multivariate claim may not be observed. For example:

Distribution of Claims, by Claim Type Observed							
Claim Combination	(y_1)	(y_2)	(y_3)	(y_1, y_2)	(y_1, y_3)	(y_2, y_3)	(y_1, y_2, y_3)
Percentage	0.4	73.2	12.3	0.3	0.1	13.5	0.2

- Traditional to predict/estimate insurance claims distributions:

$$\text{Cost of Claims} = \text{Frequency} \times \text{Severity}$$

- Joint density of the aggregate loss can be decomposed as:

$$\begin{aligned} f(N, \mathbf{M}, \mathbf{y}) &= f(N) \times f(\mathbf{M}|N) \times f(\mathbf{y}|N, \mathbf{M}) \\ \text{joint} &= \text{frequency} \times \text{conditional claim-type} \\ &\quad \times \text{conditional severity} \end{aligned}$$

- This natural decomposition allows us to investigate/model each component separately.
- Frees and Valdez (2008)**, Hierarchical Insurance Claims Modeling, *Journal of the American Statistical Association*.

- Allows for risk rating factors to be used as explanatory variables that predict both the frequency and the multivariate severity components.
- Helps capture the long-tail nature of the claims distribution through the GB2 distribution model.
- Provides for a “two-part” distribution of losses - when a claim occurs, not necessary that all possible types of losses are realized.
- Allows us to capture possible dependencies of claims among the various types through a t -copula specification.

- There is large literature on modeling claims frequency and severity
 - Klugman, Panjer and Willmot (2004) - basics without covariates
 - Kahane and Levy (*JRI*, 1975) - first to model joint frequency/severity with covariates.
 - Coutts (1984) postulates that the frequency component is more important to get right.
 - Many recent papers on frequency, e.g., Boucher and Denuit (2006)
- Applications to motor insurance:
 - Brockman and Wright (1992) - good early overview.
 - Renshaw (1994) - uses GLM for both frequency and severity with policyholder data.
 - Pinquet (1997, 1998) - uses the longitudinal nature of the data, examining policyholders over time.
 - considered 2 lines of business: claims at fault and not at fault; allowed correlation using a bivariate Poisson for frequency; severity models used were lognormal and gamma.
 - Most other papers use grouped data, unlike our work.

- Model is calibrated with detailed, micro-level automobile insurance records over eight years [1993 to 2000] of a randomly selected Singapore insurer.
 - Year 2001 data use for out-of-sample prediction
- Information was extracted from the policy and claims files.
- Unit of analysis - a registered vehicle insured i over time t (year).
- The observable data consist of
 - number of claims within a year: N_{it} , for $t = 1, \dots, T_i, i = 1, \dots, n$
 - type of claim: M_{itj} for claim $j = 1, \dots, N_{it}$
 - the loss amount: y_{itjk} for type $k = 1, 2, 3$.
 - exposure: e_{it}
 - vehicle characteristics: described by the vector \mathbf{x}_{it}
- The data available therefore consist of

$$\{e_{it}, \mathbf{x}_{it}, N_{it}, M_{itj}, y_{itjk}\}.$$

- Year: the calendar year - 1993-2000; treated as continuous variable.
- Vehicle Type: automotive (A) or others (O).
- Vehicle Age: in years, grouped into 6 categories -
 - 0, 1-2, 3-5, 6-10, 11-15, ≤ 16 .
- Vehicle Capacity: in cubic capacity.
- Gender: male (M) or female (F).
- Age: in years, grouped into 7 categories -
 - ages ≥ 21 , 22-25, 26-35, 36-45, 46-55, 56-65, ≤ 66 .
- The NCD applicable for the calendar year - 0%, 10%, 20%, 30%, 40%, and 50%.

- For the claims frequency (N_{it}), we examined several models.
 - The most complex was the random effects negative binomial count model.
 - For our data, a negative binomial model using vehicle type, age, capacity and driver gender age and NCD was most appropriate.
- For the claims type (M_{itj}), we used a multinomial logit with covariates year, vehicle year and type.

- We are particularly interested in accommodating the long-tail nature of claims.
- We use the generalized beta of the second kind (GB2) for each claim type with density

$$f(y) = \frac{\exp(\alpha_1 z)}{y|\sigma|B(\alpha_1, \alpha_2)[1 + \exp(z)]^{\alpha_1 + \alpha_2}},$$

where $z = (\ln y - \mu)/\sigma$.

- μ is a location parameter, σ is a scale parameter and α_1 and α_2 are shape parameters.
- With four parameters, the distribution has great flexibility for fitting heavy tailed data.
- Introduced by McDonald (1984), used in insurance loss modeling by Cummins et al. (1990).
- Many distributions useful for fitting long-tailed distributions can be written as special or limiting cases of the GB2 distribution; see, for example, McDonald and Xu (1995).

14/43

- Loss Modeling - Actuaries have a wealth of knowledge on fitting claims distributions. (Klugman, Panjer and Willmot, 2004, Kleiber and Kotz, 2003) (Wiley)
 - Data are often “heavy-tailed” (long-tailed, fat-tailed)
 - Extreme values are likely to occur
 - Extreme values are the most interesting - do not wish to downplay their importance via transformation
- Studies of financial asset returns is another good example Rachev et al. (2005) “Fat-Tailed and Skewed Asset Return Distributions” (Wiley)
- Healthcare expenditures - Typically skewed and fat-tailed due to a few yet high-cost patients (Manning et al., 2005, J. of Health Economics)

16/43

- We allow scale and shape parameters to vary by type and thus consider α_{1k} , α_{2k} and σ_k for $k = 1, 2, 3$.
- Despite its prominence, there are relatively few applications that use the GB2 in a regression context:
 - McDonald and Butler (1990) used the GB2 with regression covariates to examine the duration of welfare spells.
 - Beirlant et al. (1998) demonstrated the usefulness of the Burr XII distribution, a special case of the GB2 with $\alpha_1 = 1$, in regression applications.
 - Sun et al. (2008) used the GB2 in a longitudinal data context to forecast nursing home utilization.
- We parameterize the location parameter as $\mu_{ik} = \mathbf{x}'_{ik} \beta_k$:
 - Thus, $\beta_{k,j} = \partial \ln E(Y | \mathbf{x}) / \partial x_j$
 - Interpret the regression coefficients as proportional changes.

- We use a parametric copula (in particular, the t copula).
- Suppressing the $\{i\}$ subscript, we can express the joint distribution of claims (y_1, y_2, y_3) as

$$F(y_1, y_2, y_3) = H(F_1(y_1), F_2(y_2), F_3(y_3)) .$$

- Here, the marginal distribution of y_k is given by $F_k(\cdot)$ and $H(\cdot)$ is the copula.
- Modeling the joint distribution of the simultaneous occurrence of the claim types, when an accident occurs, provides the unique feature of our work.
- Some references are: Frees and Valdez (1998), Nelsen (1999).

18/43

- Analyze the risk profile of either a single individual policy, or a portfolio of these policies.
- Three different types of applications:
 - Predictive mean of losses for individual risk rating
 - allows the actuary to differentiate premium rates based on policyholder characteristics.
 - quantifies the non-linear effects of coverage modifications like deductibles, policy limits, and coinsurance.
 - possible “unbundling” of contracts.
 - Predictive distribution of portfolio of policies
 - assists insurers in determining appropriate economic capital.
 - measures used are standard: value-at-risk (VaR) and conditional tail expectation (CTE).
 - Examine effects on several reinsurance treaties
 - quota share versus excess-of-loss arrangements.
 - analysis of retention limits at both the policy and portfolio level.

19/43

- The estimated model allowed us to calculate **predictive means** for several alternative policy designs.
 - based on the 2001 portfolio of the insurer of $n = 13,739$ policies.
- For alternative designs, we considered four random variables:
 - individuals losses, y_{ijk}
 - the sum of losses from a type, $S_{i,k} = y_{i,1,k} + \dots + y_{i,N_i,k}$
 - the sum of losses from a specific event,
 $S_{EVENT,i,j} = y_{i,j,1} + y_{i,j,2} + y_{i,j,3}$, and
 - an overall loss per policy,
 $S_i = S_{i,1} + S_{i,2} + S_{i,3} = S_{EVENT,i,1} + \dots + S_{EVENT,i,N_i}$.
- These are ways of “unbundling” the comprehensive coverage, similar to decomposing a financial contract into primitive components for risk analysis.

- We also analyze modifications of standard coverage
 - deductibles d
 - coverage limits u
 - coinsurance percentages α
- These modifications alter the claims function

$$g(y; \alpha, d, u) = \begin{cases} 0 & y < d \\ \alpha(y - d) & d \leq y < u \\ \alpha(u - d) & y \geq u \end{cases} .$$

- Define $\mu_{ik} = E(y_{ijk} | N_i, K_i = k)$ from the conditional severity model with an analytic expression

$$\mu_{ik} = \exp(\mathbf{x}_{ik}'\beta_k) \frac{B(\alpha_{1k} + \sigma_k, \alpha_{2k} - \sigma_k)}{B(\alpha_{1k}, \alpha_{1k})}.$$

- Basic probability calculations show that:

$$E(y_{ijk}) = \Pr(N_i = 1) \Pr(K_i = k) \mu_{ik},$$

$$E(S_{i,k}) = \mu_{ik} \Pr(K_i = k) \sum_{n=1}^{\infty} n \Pr(N_i = n),$$

$$E(S_{EVENT,i,j}) = \Pr(N_i = 1) \sum_{k=1}^3 \mu_{ik} \Pr(K_i = k), \text{ and}$$

$$E(S_i) = E(S_{i,1}) + E(S_{i,2}) + E(S_{i,3}).$$

- In the presence of policy modifications, we approximate this using simulation (Appendix A.2).

- To illustrate the calculations, we chose at a randomly selected policyholder from our database with characteristic:
 - 50-year old female driver who owns a Toyota Corolla manufactured in year 2000 with a 1332 cubic inch capacity.
 - for losses based on a coverage type, we chose “own damage” because the risk factors NCD and age turned out to be statistically significant for this coverage type.
- The point of this exercise is to evaluate and compare the financial significance.

24 / 43

- For a single contract, the prob of zero claims is about 93%.
 - This means that the distribution has a large point mass at zero.
 - As with Bernoulli distributions, there has been a tendency to focus on the mean to summarize the distribution
- We consider a portfolio of randomly selected 1,000 policies from our 2001 (held-out) sample
- Wish to predict the distribution of $S = S_1 + \dots + S_{1000}$
 - The central limit theorem suggests that the mean and variance are good starting points.
 - The distribution of the sum is not approximately normal; this is because (1) the policies are not identical, (2) have discrete and continuous components and (3) have long-tailed continuous components.
 - This is even more evident when we “unbundle” the policy and consider the predictive distribution by type

- We consider two measures focusing on the tail of the distribution that have been widely used in both actuarial and financial work.
 - The Value-at-Risk (VaR) is simply a quantile or percentile; $Var(\alpha)$ gives the $100(1 - \alpha)$ percentile of the distribution.
 - The Conditional Tail Expectation (CTE) is the expected value conditional on exceeding the $Var(\alpha)$.
- Larger deductibles and smaller policy limits decrease the VaR in a nonlinear way.
- Under each combination of deductible and policy limit, the confidence interval becomes wider as the VaR percentile increases.
- Policy limits exert a greater effect than deductibles on the tail of the distribution
- The policy limit exerts a greater effect than a deductible on the confidence interval capturing the VaR .

**Table 7. *VaR* by Percentile and Coverage Modification

- Decompose the comprehensive coverage into more “primitive” coverages: third party injury, own damage and third party property
- Calculate a risk measure for each unbundled coverage, as if separate financial institutions owned each coverage,
- Compare to the bundled coverage that the insurance company is responsible for
- Despite positive dependence, there are still size advantages

**Table 9. *VaR* and *CTE* by Percentile
for Unbundled and Bundled Coverages**

Unbundled Coverages	<i>VaR</i>			<i>CTE</i>		
	90%	95%	99%	90%	95%	99%
Third party injury	161,476	309,881	1,163,855	592,343	964,394	2,657,911
Own damage	49,648	59,898	86,421	65,560	76,951	104,576
Third party property	188,797	209,509	264,898	223,524	248,793	324,262
Sum of Unbundled Coverages	399,921	579,288	1,515,174	881,427	1,290,137	3,086,749
Bundled (Comprehensive) Coverage	258,644	324,611	763,042	468,850	652,821	1,537,692

- A fixed percentage of each policy written will be transferred to the reinsurer
- Does not change the shape of the retained losses, only the location and scale
- Distribution of Retained Claims for the Insurer under Quota Share Reinsurance. The insurer retains 25%, 50%, 75% and 100% of losses, respectively.

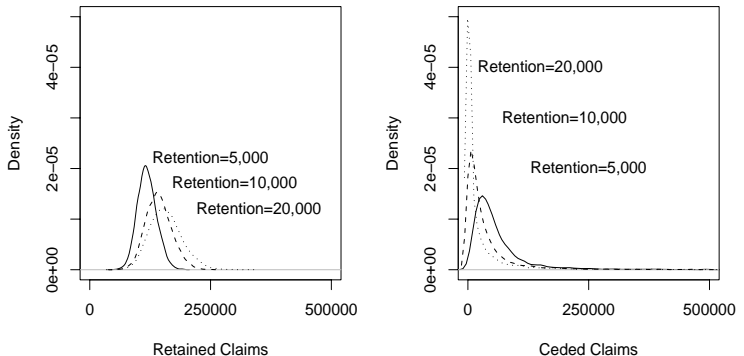

Figure: Distribution of Losses for the Insurer and Reinsurer under Excess of Loss Reinsurance. The losses are simulated under different primary company retention limits. The left-hand panel is for the insurer and right-hand panel is for the reinsurer.

- Model features

- Allows for covariates for the frequency, type and severity components
- Captures the long-tail nature of severity through the GB2.
- Provides for a “two-part” distribution of losses - when a claim occurs, all possible types of losses may not be realized.
- Allows for dependencies among claims through a copula
- Allows for heterogeneity from the longitudinal nature of policyholders (not claims)

- Recent and Ongoing Related Work

- At ISO, we are using similar models for US homeowners experience (to appear in *Astin Bulletin*)
- At ISO, we are developing measures (that we call “Gini” index) to assess out-of-sample model performance
- In *Astin Bulletin* (2010), Antonio, Frees and Valdez have compared companies’ performance using multilevel, intercompany experience
- I am working with a UW doctoral student (Winnie Sun) to examine behavior of auto and homeowners experience from a local P & C Insurer, funded by CAS.
- I am working with two UW doctoral students (Xiaoli Jin and Joyce Xiao) to implement these strategies on health care expenditures

- This paper shows how to use micro-level data to make sensible statements about “macro-effects.”
 - For example, the effect of a policy level deductible on the distribution of a block of business.
- Certainly not the first to support this viewpoint
 - Traditional actuarial approach is to development life insurance company policy reserves on a policy-by-policy basis.
 - See, for example, Richard Derrig and Herbert I Weisberg (1993) “Pricing auto no-fault and bodily injury coverages using micro-data and statistical models”
- However, the idea of using voluminous data that the insurance industry captures for making managerial decisions is becoming more prominent.
 - Gouriéroux and Jasiak (2007) have dubbed this emerging field the “microeconometrics of individual risk.”
 - See ARIA news article by Ellingsworth from ISO
- Academics need greater access to micro-level data!!
