

# Casualty Actuarial Society Loss Reserve Seminar

Patrick J. Crowe, FCAS, MAAA  
September 12, 2006

# Testing Age to Age Assumptions

---

- Regression analysis produces estimates for the standard deviation of each parameter estimated.
- Usually the absolute value of a factor is required to be at least twice its standard deviation for the factor to be regarded as significantly different from zero.
- This test is failed by many development triangles, which means that the chain ladder method is not optimal for these triangles.

# Testing Age to Age Assumptions

---

- Gary Venter's PCAS paper, "Testing the Assumptions of Age-to-Age Factors" provides the actuary with a well written documentation of the issues to be considered in deciding on a loss reserving methodology for a data set under study.

# Testing Age to Age Assumptions

---

All the materials presented in this presentation are based on the PCAS paper, “Testing the Assumptions of Age-to-Age Factors,” by Gary Venter, FCAS, MAAA.

# Testing Age to Age Assumptions

## Objective

---

- The actuary has many data, resource and time constraints in performing loss reserving analyses.
- The objective of this presentation is to develop an approach to efficiently implement the theories in his paper to allow the actuary more time to evaluate the results.

# Testing Age to Age Assumptions

---

- The *Stanard* loss generation scheme illustrates how far off reserves can be when one reserving technique is applied to losses that have an emergence process different from the one underlying the technique.
- “A simulation Test of Prediction Errors of Loss Reserve Estimation Techniques,” PCAS LXXII

# Testing Age to Age Assumptions

---

- In this exercise, we will test the assumption that the expected emergence in the next period is proportional to the losses emerged to date. To test this assumption against its alternatives, the development method that leads from each alternative needs to be fit, and then a goodness-of-fit measure applied.

# Testing Age to Age Assumptions

---

- Thomas Mack showed that some specific assumptions on the process of loss generation are needed for the chain ladder method to be optimal. Thus if actuaries find themselves in disagreement with one or another of these assumptions, they should look for some other method of development that is more in harmony with their intuition about the loss generation process.

# Chain Ladder Assumptions for Optimality

---

1. The expected value of the incremental losses to emerge in the next period is proportional to the total losses merged to date by accident year.
2. Except for the same accident year, the increments are independent.
3. The variance of the next increment observation is a function of the age and the cumulative losses to date

# Testing Age to Age Assumptions

---

- If the chain ladder fails the assumption of least squares optimality, test the underlying assumptions for the Bornhuetter-Ferguson, Cape Cod, combination of Bornhuetter-Ferguson/Cape Cod or other creative approaches that the data might suggest.

# Test the following Assumptions

---

1. Expected losses emerge proportional to losses to date
2. Expected losses emerge proportional to losses to date plus a constant
3. Expected losses emerge proportional to ultimate losses
4. Expected losses emerge as a constant
5. Expected losses emerge as a constant with an adjustment

# Testing Age to Age Assumptions

---

- The results of the tests should increase the actuary's confidence in the hypothesis, still recognizing that no hypothesis can ever be fully verified.

# Testing Age to Age Assumptions

---

- This is a work in progress. It is hoped that further research of Gary Venter's paper will foster the development of efficient testing of loss reserving approaches for the practicing actuary.
- COTOR is currently developing materials for class room instructions.

# Tests for five data sets

---

1. Auto liability, small volume
2. Auto liability, stable development
3. Part 1A, small volume
4. Part 1 H, small volume
5. Part 1 H, small volume

<b>Example 1</b> <b>Stable development, auto liability</b>
---------------------------------------------------------------

**Test of factor assumption to alternative emergence patterns**

Age	R <sup>2</sup>	Slope		t statistic	P-Value	Significant from Zero
		Coefficient	SE			
1 vs 0	20.5%	0.315	0.219	1.434	<b>0.189</b>	No
2 vs 1	30.9%	0.288	0.162	1.771	<b>0.120</b>	No
3 vs 2	71.3%	-0.077	0.020	-3.861	<b>0.008</b>	Yes
4 vs 3	50.0%	-0.077	0.035	-2.234	<b>0.076</b>	slight
5 vs 4	11.4%	0.035	0.049	0.716	<b>0.514</b>	No
6 vs 5	27.8%	0.014	0.013	1.074	<b>0.362</b>	No
7 vs 6	31.2%	0.174	0.182	0.953	<b>0.441</b>	No

**Example 5**  
**Small volume, Other liability**

**Significance of Factors**

**Linearity of Model**

**Linear Regression**

**Stability of Factors**
