### Collective Risk Model (CRM)

- Claim sizes are independent and identically distributed  $X(i)$
- Claim counts  $N$  are independent from the  $X(i)$
- Total claims  $Z=X(1) + \dots + X(N)$
  
- $EZ=EX EN$
- $VZ=VZ EN+VN (EX)^2$

---

---

---

---

---

---

---

### Simulating the CRM

- Problem: When  $EN$  is large it can take a long time to simulate  $X(1), \dots, X(N)$
- Common Solution:
  - Split claims sizes into large claim and small claims
  - Simulate large counts  $N_L$  and large claims sizes  $Y(k)$  with a CRM
    - $Z_L=Y(1) + \dots + Y(N_L)$
  - Simulate total small claims in aggregate
  - Small and Large might be left independent or correlated with a copula or other mechanism

### Correlation of Small and Large Losses for CRM

$$\rho(Z_S, Z_L) = \frac{q(1-q)E[X_S]E[X_L](\sigma^2(N) - E[N])}{\sigma(Z_S)\sigma(Z_L)}$$

**Conditional Aggregate Distribution (CAD<sub>k</sub>) Algorithm**

1. Simulate total counts  $N$
2. Simulate large counts  $N_L$  conditional on  $N$ 
  - $N_L \sim \text{Binomial}$  because  $N$  and  $X(k)$  are independent and the  $X(k)$  are iid.
  - $N_S = N - N_L$
3. Simulate large sizes  $Y(1) \dots Y(N_L)$ 
  - $F_Y(x) = F_X(x) / (1 - F(\tau))$  ( $\tau$  is the threshold between large and small losses)
  - $Z_L = Y(1) + \dots + Y(N_L)$
4. Simulate aggregate small losses conditional on  $N_S$ 
  - Simulate an approximation to  $Z_S | N_S$  by drawing from a distribution that matches the first  $k$  moments of  $Z_S | N_S$ .
  - Call this  $\tilde{Z}_S$  the CAD distribution
5. Deliver  $\{\tilde{Z}_S, Z_L(Y(1), \dots, Y(N_L))\}$

### Summary of CAD Features

- Advantages of  $CAD_k$  –
  - Fast, easy to program.
  - Preserves first  $k$  moments and Pearson correlation ( $k \geq 2$ ).
  - Provides structural method for modeling dependence of small, large losses.
- Also, apparently converges.
- That is, can observe that CAD provides good fits to  $Z_S$ .
- Here, we assume severity distribution is fixed with distribution of  $N$  depending consistently on  $\lambda$ .
- Fits are good even for "middling" values of  $\lambda$ .

### Mixed Poisson

- $N$  is a mixed Poisson if  $N \sim \text{Poisson}(\Lambda)$ , where  $\Lambda$  is a random parameter.
- Write  $\Lambda = \lambda G$ , where  $EG=1$  and  $\text{Var}G=c$ .
  - Eg – Negative Binomial,  $G \sim \text{Gamma}[1/c, c]$
  - $G$  is the mixing distribution,  $c$  the contagion parameter.
  - If  $Z$  is a mixed Poisson CRM, then so are  $Z_S, Z_L$  with same  $G$ .
  - $p(Z_S, Z_L) = c/[v(Z_S)v(Z_L)]$ ,  $v = c \cdot v$ .

---

---

---

---

---

---

---

---

### “Severity is Irrelevant”

- Limiting behavior of a mixed Poisson CRM is controlled by the mixing distribution:
- Theorem (Mildenhall): If  $Z$  is a mixed Poisson CRM then  $Z/EZ \rightarrow G$  as  $\lambda \rightarrow \infty$ .
- This is “weak convergence”, aka “convergence in distribution”

### Convergence Theorem

- Significance to CAD method: Suppose we use Gamma as the CAD-family  $Z_S$  approximating  $Z_S$ .
- Then  $Z_S = \text{Gamma}[N_S, \beta] = \sum_{1 \dots N_S} (\text{Gamma}[a, \beta])$ ,  $a, \beta$  constants.
- This converges to  $G$  by Theorem (after normalizing by the mean, of course).
- **Generalized Convergence Theorem:**  $N_k$  mixed Poisson with mixing dist  $G$ ,  $Y_n$  random variables s.t.  $EY_n = nm$ , and  $\text{Var}(Y_n) < n^2$  for  $0 < j < 2$ . Then  $Y_{N, \lambda} / (\lambda m) \rightarrow G$  as  $\lambda \rightarrow \infty$ .
- $Y_{N, \lambda}$  is defined by  $Y_{N, \lambda} | (N_k = n) = Y_n$ .
- Note: variance won't converge for  $j > 2$ .

---

---

---

---

---

---

---

---

---

### “Severity, CAD distribution are irrelevant”

- **Example 1** –  $Y_n = X_1 + \dots + X_n$ ,  $X_i$  iid. Then  $EY_n = nEX$ ,  $\text{Var}(Y_n) = n\text{Var}X$ , and  $Y_{N, \lambda}$  is CRM so get Mildenhall's theorem.
- **Example 2** – For  $\text{CAD}_k$  with  $k > 2$ , set  $Y_n = Z_S | N_S = n$ . Then  $Y_n$  satisfies theorem with  $j=1$ , and  $Y_{N, \lambda} = Z_{S_j}$  so  $Z_S$  converges to  $G$  (as does  $Z_S$ ).
- **Example 3** – Set  $Y_n = Z_S + Z_1 | (N_S = n, N_1 = B)$ , where  $B \sim \text{Bin}(n, q)$ . This shows that  $\text{CAD}_k$  converges in an overall sense for  $k > 1$ .
- Even a  $\text{CAD}_1$  method will converge as long as the variance is under control ( $j < 2$ ).
- Convergence in evidence for moderately sized portfolios.

---

---

---

---

---

---

---

---

---

---

### Convergence Theorem

- Proof of Theorem:
- Can take  $m=1$ . Must show that  $\lim_{\lambda \rightarrow \infty} \phi_{Y_{N,\lambda/\lambda}}(t) = \phi_G(t)$ , where  $\phi$  is the characteristic function  $\phi_X(t) = Ee^{itX}$ .
- Bounded Convergence Theorem allows switching Lim and E.
- Poisson characteristic function:  $e^{\lambda(e^{it}-1)}$ .
- Expand  $\phi$  in Taylor series.
- Fact (Durrett):  $\phi_X(t) = 1 + itEX + E[X^2]O(t^2)$ .

---

---

---

---

---

---

---

---

---

---

### Convergence Theorem

- Last Line of Proof:
- $$\begin{aligned} \lim \phi_{Y_{N,\lambda/\lambda}}(t) &= E[\lim E[\phi_{Y_{-1}}(t/\lambda) | G, N_{t,G} = n]] \\ &= \lim E[e^{i(t/\lambda)n} | G, N_{t,G} = n] = \lim E[e^{i\lambda G(e^{it/\lambda} - 1)}] \\ &= \lim E[e^{i\lambda G(t/\lambda + O((t/\lambda)^2))}] = \lim E[e^{itG}] = \phi_G(t). \end{aligned}$$
- 1<sup>st</sup> "=" is BCT, 2<sup>nd</sup> "=" is from earlier steps eliminating other terms with Durrett fact and  $j < 2$ ; 3<sup>rd</sup> is Poisson char. fcn.; 4<sup>th</sup> is Durrett fact applied to  $X=1$ .

---

---

---

---

---

---

---

---

---

---

### Mixed Poisson

---

---

---

---

---

---

---

---

---

---

### More Mixed Poisson

- So, choice of mixing distribution G is important - Controls characteristics of  $Z$  ( $\bar{Z}$ ),  $Z_S$  ( $\bar{Z}_S$ ), and even  $Z_L$ , to a lesser extent.
- Choices other than Gamma are allowable.
- Choice of G might reflect an assumption about skewness.
- Note, choosing Gamma is such an assumption ("skew-nu" ratio = 2).
- Paper gives parameterizations for many possibilities:
  - Usual suspects – Gamma, Lognormal (Uniform, Inverse Gaussian).
  - High-Skew – Pareto, (shifted) Exponential.
  - Discrete – Discrete Uniform, Poisson, Binomial
  - Component and shifted versions
- Adding shift drives up skewness and effective minimum value.

---

---

---

---

---

---

---

---

---

---

### CAD with Limited Information

- Generally, do not need full severity distribution to run CAD.
- Start with:  $EZ$  ( $EZ_S$ ),  $v(Z)$  ( $v(Z_S)$ ),  $\lambda(N_L)$ , severity distribution for  $Z_L$ .
- *Consistent* choice of  $\lambda, c$  is then enough to run a CAD<sub>2</sub> model.
- That is, can derive formulas for  $E[Z_S|N_S]$ ,  $v(Z_S|N_S)$  that do not involve small loss severity.
- Consistent means you do not obtain a result like  $EX_S > EX_L$ .

---

---

---

---

---

---

---

---

---

---

### CAD with Limited Information

- Derivation of Equations
  - $E[Z_S|N_S] = N_S EX_S = N_S EZ_S / \lambda(N_S) = N_S (EZ - EZ_L) / (\lambda(1-q))$  [ $q = \lambda(N_L) / \lambda$ ]
  - $v(Z_S|N_S) = v(X_S) / \text{sqrt}(N_S) = \text{sqrt}([\lambda(N_S)(v^2(Z_S) - c) - 1] / N_S) = \dots$   
 $= \text{sqrt}([\lambda(1-q)((EZ)^2(v(Z)^2 - c) - (EZ_L)^2(v(Z_L)^2 - c)) - (EZ - EZ_L)^2] / (N_S(EZ - EZ_L)^2))$

---

---

---

---

---

---

---

---

---

---

### Reinsurance Example

- Loss Assumptions:
  - Large loss threshold  $\tau = \$200k$ , max. loss =  $\$1m$ ,
  - $EZ=\$25m$ ,  $v(Z)=0.28$ ,  $\lambda(N_L)=21.5$
  - Empirical distribution for  $X_{L_i}$ ,  $\lambda=500$ ,  $c=0.0625$ .
  - Coverage on  $Z_{XoL}=Z_L - \tau N_L$ ,  $Z_{Net}=Z_S + \tau N_L$
- Coverage
  - Section 1 – Stop-Loss  $\$25m$  xs  $\$20m$  on  $Z_{Net}+50\%Z_{XoL}$ .
  - Section 2 – Coverage on remaining 50% of  $Z_{XoL}$ .
  - $Z_{XoL}$  limited to  $\$12.5m$  per section.
  - Premium =  $\$10m$  of which  $\$1.5m$  is RI margin.
  - Remainder to EA, PC = 100% of residual EA.

---

---

---

---

---

---

---

---

---

---

### Reinsurance Example

- Used Igloo software to analyze cover with nine different assumptions for the mixing distribution G.
- Analysis based on full contract cash flows – premium at time 0, mid-tail type payout patterns, discount rate = 3%.
- Rich set of outputs – Summary and percentile statistics, for NPV(Loss), NPV(PC), NPV(Income), Prob(Negative NPV), ERD, TVaR capital, RoRAC return metric.
- Also, many charts.
- Conclusion: Though results do not vary greatly, could be enough to produce different accept/reject decisions. Uniform mixing distribution is somewhat of an outlier.

---

---

---

---

---

---

---

---

---

---

### Multiple Lines of Business

- Mixed Poisson used for “common shock” correlation model.
- Here, mixing distributions are of the form  $G=G_1[c_1]G_2[c_2]$ , where G1 is the common component and the  $G_{2,i}$  are the line-specific components.
- Independent (“straight”) product with  $c_i=c_{1i}+c_{2i}+c_{1i}c_{2i}$ .
- Can also use “twisted product”:  $G_i=G_1[c_1]G_2[c_{2i}/G1]$  (Eg: ISO Risk Load Negative Binomial with parameter risk model).
- For twisted product  $c_i=c_{1i}+c_{2i}$ .
- Each formulation results in correlations  $\rho_{ij}=c_{ij}/(v_i v_j)$ .
- Multiline CAD with twisted product common shock – Can also impose correlation at CAD step.
