---

**Outline**

- Differences and similarities in medical spending across countries
- Modeling spending and data challenges
- Implications for long tailed lines of insurance

---

---

---

---

---

---

---

---

**Acknowledgements**

- Funding from the Agency for Healthcare Research and Quality
- Lots of great input
  - > Casualty Actuarial Society review committee: James Heer (chair), Avi Adler and Jeff Dollinger
  - > Indraneel Chakraborty
  - > My advisor, Mark Pauly, and my thesis committee, Scott Harrington, Greg Nini, and Jessica Wachter

**Differences and similarities across countries**

---

---

---

---

---

---

---

---

**The U.S. is different in some ways**

- High spending
  - > Absolute spending
  - > Percent of GDP
- No universal health insurance
  - > Significant uninsured minority
  - > Most developed countries have universal or near universal coverage
- Large private sector
  - > Relative to other countries
  - > Public companies concentrated in pharmaceuticals
  - > Some countries have physician private practice

---

---

---

---

---

---

---

---

**Other countries face similar challenges**

- Unsustainable rates of spending growth
- Multiple rounds of health reform
- Battling stakeholders
- Defining the role of insurance

---

---

---

---

---

---

---

---

### OECD data allows comparison across countries

- Medical spending in aggregate
  - > In national currency unit of each country
  - > On several dollar bases and PPP
- Breakdown of spending
  - > Public versus private
- Other aggregates
  - > GDP
  - > Aging and demography
- Spending data taken as given
  - > No standards across countries

---

---

---

---

---

---

---

---

### Modeling spending and modeling challenges

---

---

---

---

---

---

---

---

### U.S. spending is high

Medical spending as a share of GDP in four OECD countries

---

---

---

---

---

---

---

---

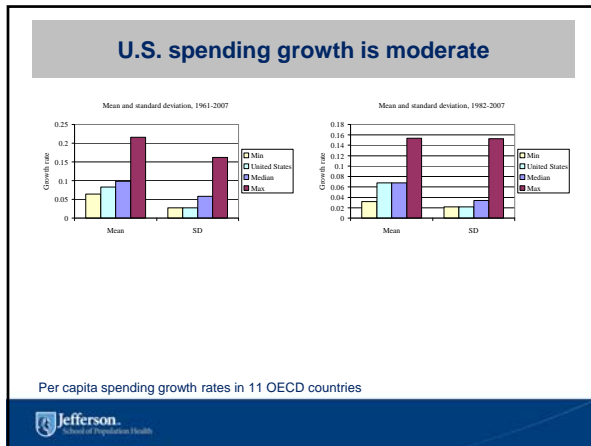

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

**Better models require a lot more data**

- Each country has approximately 50 data points
- Many moving parts
  - > Multiple policy changes
  - > Demography
  - > Macroeconomic shocks
- Strong unit roots
  - > In overall spending
  - > In the growth in spending in many countries
- High autoregressivity?
  - > It's hard to tell
  - > Possible spuriously low standard errors
- Forecast effects
  - > 1-2 years is ok
  - > 5-10 or more is a problem

---

---

---

---

---

---

---

---

---

---

**Implications for long tailed lines of insurance**

---

---

---

---

---

---

---

---

---

---

**Many lines of business have long tails**

- Guaranteed renewability
  - > Given medical trend for computing premiums
  - > Guarantee can run 10 years or more
  - > Early mistakes can be costly
- Workers' compensation
  - > Insurer may be paying many years into the future
  - > Standard of care improves
  - > Social inflation—insurers must forecast spending growth (not just inflation)
- Excess casualty reinsurance
  - > "Leveraged effect of limits on severity trend"
  - > Claims below the limit are unobserved
  - > Losses jump from zero to positive
  - > Hard to see the trend rate
  - > Excess trend can be above or below true trend rate

---

---

---

---

---

---

---

---

---

---

**Numerical example**

- Base case scenario
  - > \$10,005 of expected claims
  - > \$12,000 upfront premium
  - > Payments spread over 10 years
  - > 7% expected trend
  - > 3% discount rate, 3% return on reserves
- Gross load = 20%
  - > Initial expected gross surplus of \$1,995
  - > Final expected gross surplus of \$2,681 (nominal)

---

---

---

---

---

---

---

---

---

---

---

---

**3 alternative scenarios**

- Mean reversion in claims
  - > 9% trend in year 1 followed by return to base case nominal premiums
- Mean reversion in trend
  - > 9% trend in year 1 followed by 7% trend thereafter
- Autoregressive trend
  - > 9% trend in year 1 followed by 7.5% trend thereafter

---

---

---

---

---

---

---

---

---

---

---

---

**Persistent trend growth can cause variation from expectations for a 10 year insurance contract**

Scenario	Naive premium	Total discounted claims	Final gross surplus	Time 0 gross surplus	Time 0 gross load
Base case	12000	10005	2681	1995	20%
Mean reverting claims	12000	10021	2659	1979	20%
Mean reverting trend	12000	10215	2400	1785	17%
Autoregressive trend	12000	10436	2101	1564	15%

Full insurance case

---

---

---

---

---

---

---

---

---

---

---

---

**Persistent trend growth can cause losses for a 10 year reinsurance contract**

Scenario	Naive premium	Total discounted claims	Final gross surplus	Time 0 gross surplus	Time 0 gross load
Base case	2400	2001	536	399	20%
Mean reverting claims	2400	2014	519	386	19%
Mean reverting trend	2400	2193	278	207	9%
Autoregressive trend	2400	2403	-3	-3	0%

20% excess reinsurance case

---

---

---

---

**There are some solutions to forecast errors in medical spending**

- Prediction markets
  - > Bet on aggregates
  - > Bet on political outcomes
  - > Hard to connect to different future trend outcomes
- TIPS
  - > Inflation hedging bonds
  - > Could be "sliced" to be medical only
  - > Doesn't hedge against quantity changes (most of trend growth)
- Macromarkets
  - > Buy shares in GDP, medical spending growth
  - > Health insurance futures haven't worked
- Government reinsurance for health insurance
  - > Could exacerbate problems in other lines linked to medical care

---

---

---

---

---

---

---

---

---

---

---

---

**Many problems with medical spending are out of our hands**

- Medical spending is linked to overall economic growth
- Medical trend is not outrageous in the U.S.
  - > Trend = GDP growth + Rate of aging
  - > Fits prior trend well
- GDP growth, demography even less controllable
- PPACA
  - > May fix some problems
  - > Some problems may spill over from health insurance to other medical claims linked lines

---

---

---

---

---

---

---

---

---

---

---

---

**The best solutions involve humility**

- PPACA—new business opportunities
  - > ACOs will need risk management services
  - > Chances to profitably manage new populations?
- Challenges involve an uncertain future
  - > Will we get more volatility like other countries with publicly funded health care?
  - > Significant trend volatility to deal with here and abroad
  - > Trend breaks and implications for long tailed lines
- Public policy implication—exercise caution
  - > In making public policy
  - > In writing long tailed insurance and reinsurance tied to medical claims

---

---

---

---

---

---

---

---

**Next steps**

- Paper is available in the CAS E-Forum
  - > <http://www.casact.org/pubs/forum/11spforum/>
- I continue to work on this problem
- I have a grant proposal in to The Commonwealth Fund to extend this work
  - > Look at financial and non financial similarities of international health care systems
  - > Convergence of systems over time

---

---

---

---

---

---

---

---
