# GLM I An Introduction to Generalized Linear Models

CAS Ratemaking and Product Management Seminar March 2012

Presented by: Tanya D. Havlicek, ACAS, MAAA

## **ANTITRUST Notice**

The Casualty Actuarial Society is committed to adhering strictly to the letter and spirit of the antitrust laws. Seminars conducted under the auspices of the CAS are designed solely to provide a forum for the expression of various points of view on topics described in the programs or agendas for such meetings.

Under no circumstances shall CAS seminars be used as a means for competing companies or firms to reach any understanding – expressed or implied – that restricts competition or in any way impairs the ability of members to exercise independent business judgment regarding matters affecting competition.

It is the responsibility of all seminar participants to be aware of antitrust regulations, to prevent any written or verbal discussions that appear to violate these laws, and to adhere in every respect to the CAS antitrust compliance policy.

## Outline

- Overview of Statistical Modeling
- Linear Models
  - ANOVA
  - Simple Linear Regression
  - Multiple Linear Regression
  - Categorical Variables
  - Transformations
- Generalized Linear Models
  - Why GLM?
  - From Linear to GLM
  - Basic Components of GLM's
  - Common GLM structures
- References

#### **Generic Modeling Schematic**

#### **Basic Linear Model Structures - Overview**

Simple ANOVA :

-  $Y_{ij} = \mu + e_{ij}$  or more generally  $Y_{ij} = \mu + \psi_i + e_{ij}$ 

- In Words: Y is equal to the mean for the group with random variation and possibly fixed variation
- Traditional Classification Rating Group Means
- Assumptions: errors independent & follow  $N(0,\sigma_e{}^2\,)$
- $-\sum \psi_i = 0$  *i* = 1,...,k (fixed effects model)
- $\psi_i \sim N(0, \sigma_{\psi}^2)$  (random effects model)

#### Basic Linear Model Structures - Overview

- Simple Linear Regression :  $y_i = b_o + b_1x_i + e_i$ 
  - Assumptions:
    - linear relationship
    - errors independent and follow  $N(0,\sigma_e^2)$
- Multiple Regression :  $y_i = b_o + b_1 x_{1i} + \dots + b_n x_{ni} + e_i$ 
  - Assumptions: same, but with n independent random variables (RV's)
- Transformed Regression : transform x, y, or both; maintain errors are N(0,σe<sup>2</sup>)

 $y_i = \exp(x_i) \rightarrow \log(y_i) = x_i$ 

Simple Regression (special case of multiple regression)

- Model:  $Y_i = b_o + b_1 X_i + e_i$ 
  - Y is the dependent variable explained by X, the independent variable
  - Y could be Pure Premium, Default Frequency, etc
  - Want to estimate relationship of how Y depends on X using observed data
  - Prediction:  $Y = b_0 + b_1 x^*$  for some new x\* (usually with some confidence interval)

- A formalization of best fitting a line through data with a ruler and a pencil

Note: All data in this presentation are for illustrative purposes only

#### **Regression – Observe Data**

#### Estimated Effect of Equity on Default

8

### Regression – Observe Data

#### Regression – Observe Data

ANOVA

	df	SS	MS	F	Significance F
Regression	1	52.7482	52.7482	848.2740	<0.0001
Residual	17	1.0571	0.0622		
Total	18	53.8053			

• How much of the sum of squares is explained by the regression? SS = Sum Squared Errors SSTotal = SSRegression + SSResidual (Residual also called Error) SSTotal =  $\sum (y_i - \overline{y})^2 = 53.8053$ 

SSRegression =  $b_{1 est}^{*} [\sum X_i y_i - 1/n(\sum X_i)(\sum y_i)] = 52.7482$ 

SSResidual =  $\sum (y_i - y_{i est})^2$ 

= SSTotal – SSRegression

1.0571 = 53.8053 - 52.742

#### ANOVA

	df	SS	MS	F	Significance F
Regression	1	52.7482	52.7482	848.2740	<0.0001
Residual	17	1.0571	0.0622		
Total	18	53.8053			
Re	gre	ession S	Statistics	S	
Multiple F	2			0.9901	<ul> <li>MS = SS divided by df</li> </ul>
R Square	;			0.9804	<u>R<sup>2</sup></u> : (SS Regression/SS Total)
Adjusted	RS	Square		0.9792	0.9804 = 52.7482 / 53.8053
					<ul> <li>percent of variance explained</li> </ul>

- <u>F statistic</u>: (MS Regression/MS Residual)
- significance of regression:
  - F tests H<sub>o</sub>: b<sub>1</sub>=0 v. H<sub>A</sub>: b<sub>1</sub>≠0

	Coefficients	Standard Error	t Stat	P-value	Lower 95%	Upper 95%	Lower 95.0%	Upper 95.0%
Intercept	3.3630	0.0730	46.0615	0.0000	3.2090	3.5170	3.2090	3.5170
Х	-0.0828	0.0028	-29.1251	0.0000	-0.0888	-0.0768	-0.0888	-0.0768

<u>T statistics</u>:  $(b_{i est} - H_o(b_i)) / s.e.(b_{i est})$ 

- significance of individual coefficients
- $T^2 = F$  for  $b_1$  in simple regression
- $(-29.1251)^2 = 848.2740$
- F in multiple regression tests that at least one coefficient is nonzero. For the simple case, at least one is the same as the entire model. F stat tests the global null model.

#### **Residuals Plot**

- Looks at (y<sub>obs</sub> y<sub>pred</sub>) vs. y<sub>pred</sub>
- Can assess linearity assumption, constant variance of errors, and look for outliers
- Standardized Residuals (raw residual scaled by standard error) should be random scatter around 0, standard residuals should lie between -2 and 2
- With small data sets, it can be difficult to assess assumptions

#### Normal Probability Plot

- Can evaluate assumption  $e_i \sim N(0, \sigma_e^2)$ 
  - Plot should be a straight line with intercept  $\mu$  and slope  $\sigma_e{}^2$
  - Can be difficult to assess with small sample sizes

### Residuals

- If absolute size of residuals increases as predicted value increases, may indicate nonconstant variance
- May indicate need to transform dependent variable
- May need to use weighted regression
- May indicate a nonlinear relationship

#### **Distribution of Observations**

- Average claim amounts for Rural drivers are normally distributed as are average claim amounts for Urban drivers
- Mean for Urban drivers is twice that of Rural drivers
- The variance of the observations is equal for Rural and Urban
- The total distribution of average claim amounts across Rural and Urban is not Normal
  - here it is bimodal

**Distribution of Individual Observations** 

#### **Distribution of Observations**

- The basic form of the regression model is  $Y = b_o + b_1 X + e$
- $\mu_i = E[Y_i] = E[b_o + b_1X_i + e_i] = b_o + b_1X_i + E[e_i] = b_o + b_1X_i$
- The mean value of Y, rather than Y itself, is a linear function of X
- The observations  $Y_i$  are normally distributed about their mean  $\mu_i Y_i \sim N(\mu_i, \sigma_e^2)$
- Each Y<sub>i</sub> can have a different mean  $\mu_i$  but the variance  $\sigma_e^2$  is the same for each observation

18

## Multiple Regression (special case of a GLM)

- $Y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \dots + \beta_n X_n + \varepsilon$
- E[Y] = <u>β</u> X

 $\underline{\beta}$  is a vector of the parameter coefficients

 $\underline{Y}$  is a vector of the dependent variable

**X** is a matrix of the independent variables

- Each column is a variable
- Each row is an observation
- Same assumptions as simple regression
  - 1) model is correct (there exists a linear relationship)
  - 2) errors are independent
  - 3) variance of  $e_i$  constant
  - 4)  $e_i \sim N(0, \sigma_e^2)$
- Added assumption the n variables are independent

- Uses more than one variable in regression model
  - R-sq always goes up as add variables
  - Adjusted R-Square puts models on more equal footing
  - Many variables may be insignificant
- Approaches to model building
  - Forward Selection Add in variables, keep if "significant"
  - Backward Elimination Start with all variables, remove if not "significant"
  - Fully Stepwise Procedures Combination of Forward and Backward

- Goal : Find a simple model that explains things well with assumptions reasonably satisfied
- Cautions:
  - All predictor variables assumed independent
    - as add more, they may not be
    - multicollinearity— linear relationships among the X's
  - Tradeoff:
    - Increase # of parameters (1 for each variable in regression) → lose degrees of freedom (df)
    - keep df as high as possible for general predictive power → problem of over-fitting

- Model: Claim Rate = f (Loan-to-Value (LTV), Delinquency Status, Home Price Appreciation (HPA))
- Degrees of freedom ~ # observations # parameters
- Any parameter with a t-stat with absolute value less than 2 is not significant SUMMARY OUTPUT

Regression S	tatistics

T-stats are also used for evaluating significance of coefficients in GLM's

Residuals Plot

Residual Plots are also used to evaluate fits of GLM's

Normal Probability Plot

Percentile or Quantile Plots are also used to evaluate fits of GLM's

### Categorical Variables (used in LM's and GLM's)

- Explanatory variables can be discrete or continuous
- Discrete variables generally referred to as "factors"
- Values each factor takes on referred to as "levels"
- Discrete variables also called Categorical variables
- In the multiple regression example given, all variables were categorical except HPA

### **Categorical Variables**

- Assign each level a "Dummy" variable
  - A binary valued variable
  - X=1 means member of category and 0 otherwise
  - Always a reference category
    - defined by being 0 for all other levels
  - If only one factor in model, then reference level will be intercept of regression
  - If a category is not omitted, there will be linear dependency
    - "Intrinsic Aliasing"

#### **Categorical Variables**

- Example: Loan To Value (LTV)
  - Grouped for premium 5 Levels
    - <=85%, LTV85
    - 85.01% 90%, LTV90
    - 90.01% 95%, LTV95
    - 95.01% 97%, LTV97
    - >97% Reference
  - Generally positively correlated with claim frequency
  - Allowing each level it's own dummy variable allows for the possibility of non-monotonic relationship
  - Each modeled coefficient will be relative to reference level

### Transformations

- A possible solution to nonlinear relationship or unequal variance of errors
- Transform predictor variables, response variable, or both
- Examples:
  - Y' = log(Y)
  - X' = log(X)
  - X' = 1/X
  - Y' =  $\sqrt{Y}$
- Substitute transformed variable into regression equation
- Maintain assumption that errors are  $N(0,\sigma_e^2)$

## Why GLM?

- What if the variance of the errors increases with predicted values?
  - More variability associated with larger claim sizes
- What if the values for the response variable are strictly positive?
  - assumption of normality violates this restriction
- If the response variable is strictly non-negative, intuitively the variance of Y tends to zero as the mean of X tends to zero
  - Variance is a function of the mean (poisson, gamma)
- What if predictor variables do not enter additively?
  - Many insurance risks tend to vary multiplicatively with rating factors

#### **Classic Linear Model to Generalized Linear Model**

#### ■ <u>LM</u>:

- X is a matrix of the independent variables
  - Each column is a variable
  - Each row is an observation
- <u>β</u> is a vector of parameter coefficients
- $\underline{\epsilon}$  is a vector of residuals

#### • <u>GLM</u>:

- **Χ**, <u>β</u> same as in LM
- <u></u>*ɛ* is still vector of residuals
- g is called the "link function"

 $\underline{LM}$   $\underline{Y} = \underline{\beta} \mathbf{X} + \underline{\varepsilon}$   $E[\underline{Y}] = \underline{\beta} \mathbf{X}$   $E[\underline{Y}] = \underline{\mu} = \underline{\eta}$ 

 $\boldsymbol{\varepsilon} \thicksim \mathsf{N}(0, \sigma_{\mathrm{e}^2})$ 

#### <u>GLM</u>

 $g(\underline{\mu}) = \underline{\eta} = \underline{\beta} \mathbf{X}$  $E[\underline{Y}] = \underline{\mu} = g^{-1}(\underline{\eta})$  $\underline{Y} = g^{-1}(\underline{\eta}) + \underline{\varepsilon}$  $\varepsilon \sim \text{exponential family}$ 

## Classic Linear Model to Generalized Linear Model

■ <u>LM</u>:

- 1) Random Component : Each component of <u>Y</u> is independent and normally distributed. The mean  $\mu_i$  allowed to differ, but all Y<sub>i</sub> have common variance  $\sigma_e^2$
- 2) Systematic Component : The n covariates combine to give the "linear predictor"

<u>п</u> = <u>в</u> Х

3) *Link Function* : The relationship between the random and systematic components is specified via a link function. In linear model, link function is identity fnc.

- GLM:
  - 1) Random Component : Each component of <u>Y</u> is independent and from one of the exponential family of distributions
  - 2) Systematic Component : The n covariates are combined to give the "linear predictor"

*3) Link Function* : The relationship between the random and systematic components is specified via a link function g, that is differentiable and monotonic

$$\mathsf{E}[\underline{\mathsf{Y}}] = \underline{\mu} = g^{-1}(\underline{n})$$

## Linear Transformation versus a GLM

- Linear transformation uses transformed variables
  - GLM transforms the mean
  - GLM not trying to transform Y in a way that approximates uniform variability

- The error structure
  - Linear transformation retains assumption  $Y_i \sim N(\mu_i, \sigma_e^2)$
  - GLM relaxes normality
  - GLM allows for non-uniform variance
  - Variance of each observation  $Y_i$  is a function of the mean  $E[Y_i] = \mu_i$

#### The Link Function

- Example: the log link function g(x) = ln(x);  $g^{-1}(x) = e^x$
- Suppose Premium (Y) is a multiplicative function of Policyholder Age  $(X_1)$  and Rating Area  $(X_2)$  with estimated parameters  $\beta_1$ ,  $\beta_2$ 
  - $\eta_i = \beta_1 X_1 + \beta_2 X_2$
  - $g(\mu_i) = \eta_i$
  - $E[Y_i] = \mu_i = g^{-1}(\eta_i)$
  - $E[Y_i] = \exp(\beta_1 X_1 + \beta_2 X_2)$
  - $\mathsf{E}[\underline{Y}] = g^{-1}(\underline{\beta} \mathbf{X})$
  - $\mathsf{E}[\mathsf{Y}_i] = \exp(\beta_1 \mathsf{X}_1) \cdot \exp(\beta_2 \mathsf{X}_2) = \mu_i$
  - $g(\mu_i) = \ln [\exp (\beta_1 X_1) \cdot \exp(\beta_2 X_2)] = \eta_i = \beta_1 X_1 + \beta_2 X_2$
  - The GLM here estimates logs of multiplicative effects

#### **Examples of Link Functions**

- Identity
  - -g(x) = x  $g^{-1}(x) = x$  additive rating plan
- Reciprocal
  - -g(x) = 1/x  $g^{-1}(x) = 1/x$
- Log
  - g(x) = ln(x)  $g^{-1}(x) = e^{x}$  multiplication
    - multiplicative rating plan

Logistic

 $- g(x) = \ln(x/(1-x)) \qquad g^{-1}(x) = e^{x}/(1+e^{x})$ 

#### **Error Structure**

- Exponential Family
  - Distribution completely specified in terms of its mean and variance
  - The variance of  $Y_i$  is a function of its mean  $E[Y_i] = \mu_i$
  - Var  $(Y_i) = \varphi V(\mu_i) / \omega_i$
  - $V(\mu)$  structure specifies the *distribution* of Y, but
  - $V(\mu)$ , the variance function, is not the variance of Y
  - $\phi$  is a parameter that scales the variance
  - $-\omega_i$  is a constant that assigns a weight, or credibility, to observation i

### **Error Structure**

- Members of the Exponential Family
  - Normal (Gaussian) -- used in classic regression
  - Poisson (common for frequency)
  - Binomial
  - Negative Binomial
  - Gamma (common for severity)
  - Inverse Gaussian
  - Tweedie (common for pure premium)
    - aka Compound Gamma-Poisson Process
      - Claim count is Poisson distributed
      - Size-of-Loss is Gamma distributed

## General Examples of Error/Link Combinations

- Traditional Linear Model
  - response variable: a continuous variable
  - error distribution: normal
  - link function: identity
- Logistic Regression
  - response variable: a proportion
  - error distribution: binomial
  - link function: logit
- Poisson Regression in Log Linear Model
  - response variable: a count
  - error distribution: Poisson
  - link function: log
- Gamma Model with Log Link
  - response variable: a positive, continuous variable
  - error distribution: gamma
  - link function: log

#### Specific Examples of Error/Link Combinations

Observed Response	Link Fnc	Error Structure	Variance Fnc
Claim Frequency	Log	Poisson	μ
Claim Severity	Log	Gamma	μ²
Pure Premium	Log	Tweedie	µ <sup>p</sup> (1 <p<2)< td=""></p<2)<>
Retention Rate	Logit	Binomial	μ(1-μ)
